## Diagnosis of Discrete Event Systems (DES)

1. Diagnosis by computing belief states
2. Off-line computation: number of belief states makes it inapplicable for real-world problems
3. Symbolic and propositional logic using Binary Decision Diagram is subject to exponential blow-up in space.
4. Pre-computation of belief states takes exponential running time and has an exponential size in the number of states.

## New Time-Windows Algorithms

1. Time windows only consider most recent observations
2. Motivations and benefits:
  - (1) flexibility: independent diagnosis analyses on separate time windows and skips irrelevant time windows
  - (2) reduce diagnosis complexity: more manageable and build a diagnoser of polynomial size
  - (3) precision loss? Precision is tested.
3. DES model: [Figure 1](#) shows an Automaton
4. Diagnosis indicates whether system is in nominal mode or in faulty mode. Diagnoser assumes that system is not faulty unless proved otherwise.
5. [Table 1](#) and [2](#) show two examples Window-based Diagnosis and demonstrate the importance to decide which algorithm to use and size of time window.

Figure 1. DES Model: *F* is a faulty state. Other states are nominal. *a, b, c* are observable events. *u, v* are unobservable.

Observation	Slice	Diagnosis	Output
<i>a, b, b, b, b, c, c, c</i>	<i>(a, b, b, b)</i>	<i>N</i>	<i>N</i>
<i>a, b, b, b, a, c, c, c</i>	<i>(b, c, c, c)</i>	<i>N</i>	<i>N</i>
<i>a, b, b, b, a, c, c, c</i>	<i>(a, b, b, b)</i>	<i>F</i>	<i>F</i>
<i>a, b, b, b, a, c, c, c</i>	<i>(a, c, c, c)</i>	<i>F</i>	<i>F</i>
<i>b, a, b, a, c, c, c, c</i>	<i>(b, a, b, a)</i>	<i>N</i>	<i>N</i>
<i>b, a, b, a, c, c, c, c</i>	<i>(c, c, c, c)</i>	<i>N</i>	<i>N</i>

Table 1: Algorithm 1 (AI<sub>1</sub>) slices a sequence of observations every 4 observations.

Input	Slice	Diagnosis	Output
<i>a, b, b, b, b, c, c, c</i>	<i>(a, b, b, b)</i>	<i>N</i>	<i>N</i>
<i>a, b, b, b, b, c, c, c</i>	<i>(b, b, b, c)</i>	<i>N</i>	<i>N</i>
<i>a, b, b, b, b, c, c, c</i>	<i>(b, c, c, c)</i>	<i>N</i>	<i>N</i>
<i>a, b, b, b, a, c, c, c</i>	<i>(a, b, b, b)</i>	<i>N</i>	<i>F</i>
<i>a, b, b, b, a, c, c, c</i>	<i>(b, b, a, c)</i>	<i>F</i>	<i>F</i>
<i>a, b, b, b, a, c, c, c</i>	<i>(a, c, c, c)</i>	<i>F</i>	<i>F</i>
<i>b, a, b, a, c, c, c, c</i>	<i>(b, a, b, a)</i>	<i>N</i>	<i>F</i>
<i>b, a, b, a, c, c, c, c</i>	<i>(b, a, c, c)</i>	<i>F</i>	<i>F</i>
<i>b, a, b, a, c, c, c, c</i>	<i>(c, c, c, c)</i>	<i>N</i>	<i>N</i>

Table 2: Algorithm 2 (AI<sub>2</sub>) slices a sequence of observations every 4 observations and time windows overlap. AI<sub>1</sub> has drawbacks of imprecise diagnosis as it could not diagnose fault in the third observation.

## Verify precision of diagnosis algorithms using simulation

1. Measure precision of Time-Window Algorithms
2. Build simulation *si* (*M, A*) for model (*M*) and diagnostic algorithm (*A*). [Figure 2](#) illustrates AI<sub>1</sub> simulation for DES model in [Figure 1](#).

## Experiments and results

1. Use Binary Decision Diagram to test diagnosability of model and precision of windows-based algorithms.
2. Example of factory operations: [Figure 3](#) shows central model *Mc* dispatching a job (*ai*) to operation plants (*Mi*) and receiving feedback (*ei*). If *Mc* enters faulty scenario, only *e1* will be observed from *M1*.
3. In [Figure 4](#), results show that they are all diagnosable.

## Future work

1. “Backbone” diagnosis: remember what we know for sure
2. How to find root cause of ambiguity?
3. Create a benchmark for experiments

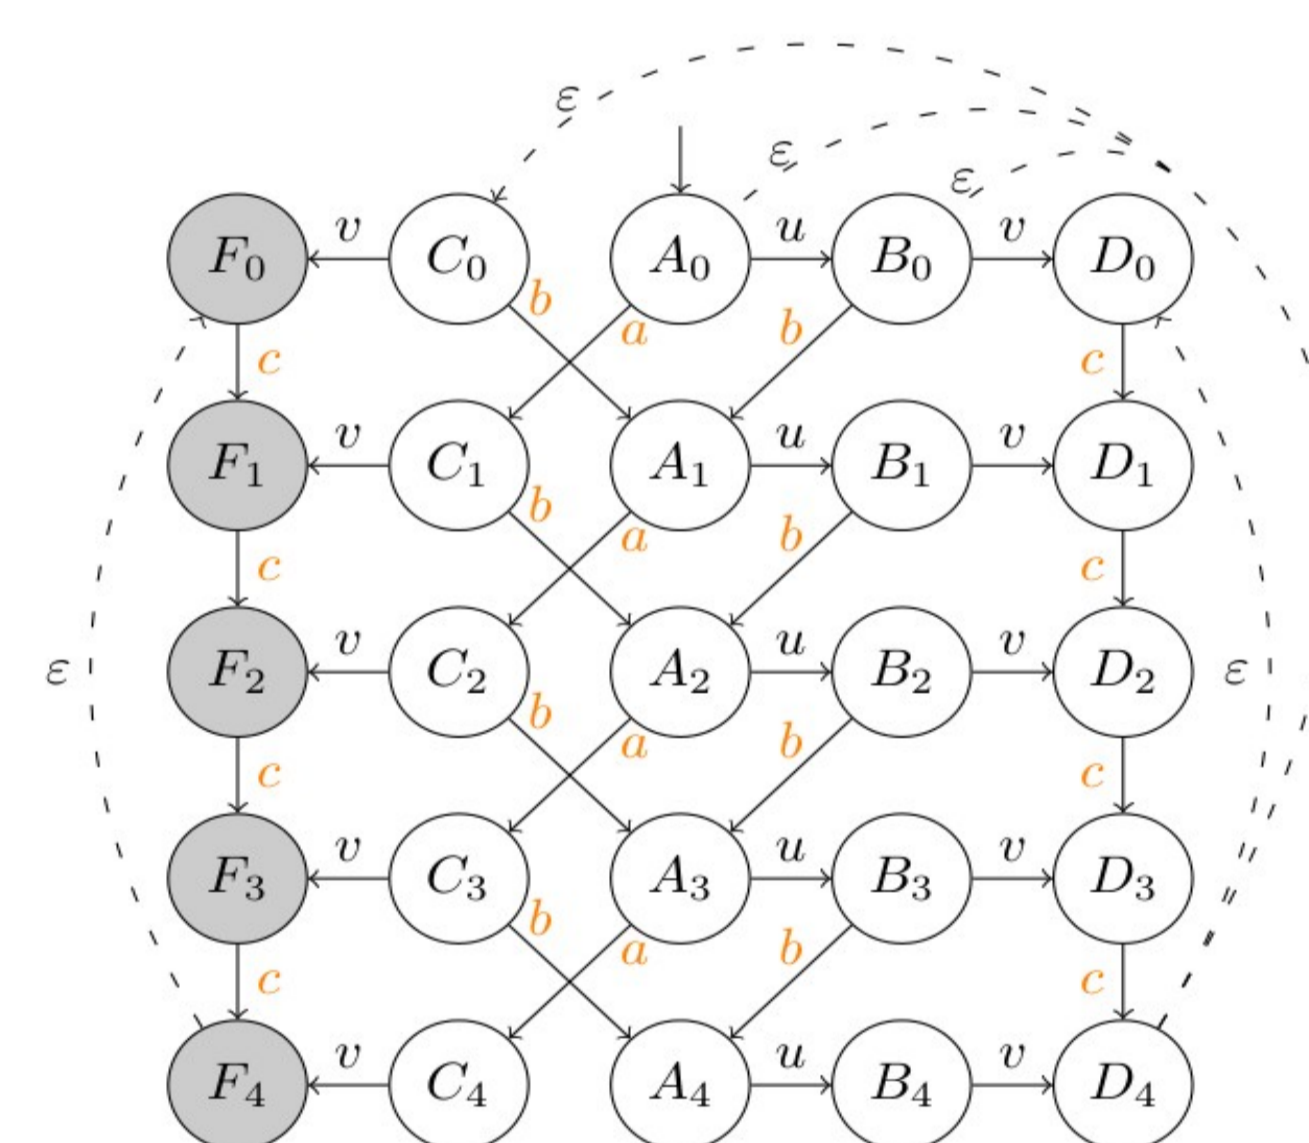

Figure 2. Part of Algorithm 1 simulation: Dotted lines also need to link *A<sub>4</sub>* to *A<sub>0</sub>*, *B<sub>0</sub>*, *C<sub>0</sub>* and *D<sub>0</sub>*. Same applies to *B<sub>4</sub>* and *C<sub>4</sub>*.

Figure 3. Example of factory operations

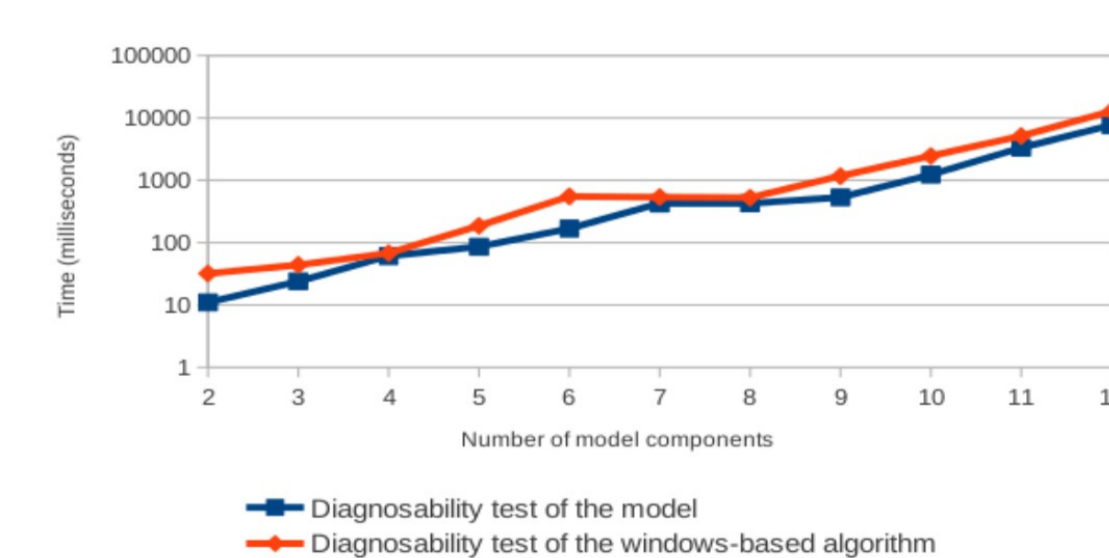

Figure 4. Running time of precision tests
